ABSTRACT

Benign prostatic hyperplasia (BPH) is one of the most common benign tumors in men with prevalence ranging from 50% for men in their 60s to 90% for men in their 80s. The researcher sought to determine the relationship of prostate-specific antigen (PSA) and prostate volume in patients with benign prostatic hyperplasia. This study was based on 33 cases of benign prostatic hyperplasia in the Department of Urology, RSUD Dr. Soetomo Surabaya that diagnosed by histopathology examination. Cases with malignancy, acute urinary retention, and prostatitis were excluded. The variables of prostate-specific antigen and prostate volume were examined. The results of this study found that 33 men were enrolled with mean PSA 16.04 ng/ml and a mean prostate volume of 49.13 ml. Overall, 84.8% had PSA level >4 ng/ml and 90.9% had prostate volume >25 ml. Prostate-specific antigen has significant correlation with prostate volume (p=0.019; r=0.362). This study concluded that prostate-specific antigen and prostate volume showed a significant correlation.
INTRODUCTION

Benign prostatic hyperplasia (BPH) is a histological diagnosis associated with uncontrolled proliferation of connective tissue, smooth muscle, and epithelial glands of the prostate gland resulting in increased prostate volume (Parsons & Patel, 2014). More specifically, prostate enlargement occurs due to hyperplasia of the stromal and epithelial glands that occur in the periurethral transition zone of the prostate gland (Dhingra & Bhagwat, 2011). This condition causes the urethra pars prostatic depressed and it will inhibit the flow of urine when emptying the bladder. Disruption of urine flow in BPH causes symptoms such as frequency, urgency, nocturia, intermittence, decreased flow, and hesitation (Kapoor, 2012).

Genetic, dietary, and lifestyle factors play an important role in the growth process of BPH. Recent research shows that there is a strong association between clinical BPH and metabolic syndrome, erectile dysfunction, and inflammation (Lim, 2017). The incidence of BPH is very much related to age. Prostate enlargement begins when a man turns around 40 years old. The prevalence of BPH from histology shows positive results in approximately 8% of men in their 40s, 50% in their 60s, and 80% in their 90s (Lim, 2017).

Prostate volume is an indicator of BPH and progression therapeutic response given. Transrectal ultrasonography (TRUS) is the most accurate method for assessing the shape and volume of prostate examination. The TRUS examination includes a routine examination for BPH patients (Mochtar et al., 2015).

Serum prostate-specific antigen (PSA) tests are performed for health screening and early detection of prostate cancer. PSA measurement should be performed only if a diagnosis of prostate cancer will change the management or if PSA can assist in decision-making in patients at risk of progression of BPH (Mochtar et al., 2015). Serum PSA is a marker of prostatic gland epithelial cell activity. Increased serum PSA levels often indicate abnormalities of the prostate (Kowalkouski, Goltz, Hart, & Latin1, 2013). This shows that in addition to prostate volume, serum PSA also has a relationship with BPH in terms of predicting progression. Much research has been done in various countries regarding the relationship between PSA and prostate volume, but not many similar studies have been done in Indonesia, especially in Surabaya. Our research aims to analyze the relationship between serum PSA and prostate volume in patients diagnosed with BPH through histopathological examination.

METHODS

This study was an observational analytic study with a cross-sectional approach conducted in the case of BPH at the Urology Polyclinic Dr. Soetomo Surabaya in January 2017 - December 2018. The inclusion criteria of this study were: (1) BPH was diagnosed based on histopathological examination results, (2) data on the results of PSA examination in medical records and (3) data on the results of the TRUS examination was recorded in medical records. Patients diagnosed with BPH with malignancy, acute urinary retention and / or prostatitis were excluded from the study data.

Serum PSA samples of patients were processed using ADVIA-Centaur XPT by the direct chemiluminometric method in the Clinical Pathology laboratory of Dr. RSUD Hospital Soetomo Surabaya. The prostate volume calculation formula used is a prolate ellipsoid. The formula used to calculate prostate size is height (anteroposterior) x width (transversal) x length (cephalocaudal) x (π / 6) (Haverkamp et al., 2019). Determination of the relationship between serum PSA and prostate volume using
the Spearman statistical test with statistical analysis was significant when p <0.05. This study has received ethical approval from the Health Research Ethics Committee Dr. Soetomo Surabaya (0620 / KEPK / IX / 2018).

RESULTS
Samples were collected from 33 patients who met the inclusion and exclusion criteria. All patients were male with various age ranges. The average age, serum PSA and prostate volume are shown in Table 1.

The average age of patients diagnosed with BPH was 64.81 years (SD 7.06, age range 53-80 years), 2 (6.1%) were in the age range 46-55 years, 20 (60.6%) were in the age range of 56 - 65 years and 11 (33.3%) were in the age range> 65 years. The relationship between age, serum PSA and prostate volume of 33 BPH patients is summarized in Table 2.

The average serum PSA was 16.04 ng/dl (SD 6.23, serum PSA range 2.20 - 80.40 ml). The majority of serum PSA BPH patients (84.8%)> 4 ng/dl. The average prostate volume is 49.13 ml (SD 18.60, volume range 14.3 - 95.7 ml). The majority of BPH patients (90.9%) have prostate volume> 25 ml. There was a strong relationship between serum PSA and prostate volume (Spearman correlation coefficient r = 0.362, p <0.05). The relationship between serum PSA and prostate volume in BPH patients are shown in Table 3.

DISCUSSION

A total of 33 data from patient medical records have been verified as inclusion data from this study. This study found that the majority of BPH events occurred in the age range of 56 - 65 years, with an average age of 64.81 years. These results are consistent with research conducted by Al-Khalil et al. (2016), of the 130 BPH cases found, 86 were aged 66-69 years. Another recent study by Krisna, Maulana, & Kresnoadi (2017) stated that the average age of BPH patients in their study was 64.32 years. These findings indicate that the risk of BPH events in men increases in old age.

This study showed that as many as 84.8% of BPH patients had PSA levels exceeding the normal limit (> 4 ng/dl) and the remaining 15.2% had PSA levels within the normal range (≤4 ng/dl). These results are consistent with the results of research conducted by Liu, Tang, Gong, & Kong (2017) which states that BPH patients with PSA levels> 4 ng/dl are more numerous than BPH patients with PSA levels ≤4 ng/dl both before surgery and after surgery. Other studies that also support this result are studies by Rybalov et al. (2013) which states that 171 of the 245 BPH patients studied had PSA levels> 4 ng/dl. In another similar study conducted by Erdogan et al. (2019), the average PSA level was 9.3 ng/dl from a total of 137 BPH data obtained. Research conducted in Indonesia by Putra et al. (2016) on 1,638 BPH patients found an average PSA level of 4.93 ng/dl. This study obtained data with an average PSA level that is far different from the existing research, with a difference of about 11.1 - 6.73 ng/dl. This difference is due to the different research methods used. In a study conducted by Erdogan et al. (2019) has exclusion criteria for PSA levels of more than 30 ng/dl. In a study conducted by Putra et al. (2016) established exclusion criteria for PSA levels of more than 10 ng/dl. Research conducted at RSUD Dr. Soetomo uses a different method from the research mentioned above. The difference is that in this study, there is no maximum limit of PSA levels in the exclusion criteria so that the research results obtained are not the same as the existing research.

This study showed that as many as 90.9% of BPH patients had a prostate volume exceeding the normal limit (> 25 ml), and the remaining 9.1% had a prostate volume within the normal limit (≤25 ml). These results are consistent with research conducted by Deori, Das, & Rahman (2017) which states that 27.5% of BPH patients have prostate volume ≤30 ml, while the remaining 72.5% have prostate volume > 30 ml. The highest volume frequency distribution is in the range of 40 - 60 ml, as many as 13 patients (39.4%). The average prostate volume in this study was 49.68 ml. Research conducted by Mao et al. (2009) in China stated that the average prostate volume of 268 BPH patients was 42.45 ml. Putra et al. (2016) research in Indonesia states that the average prostate volume of 666 BPH patients with indwelling catheters is 47.58 ml, while the average prostate volume of 972 BPH patients without indwelling catheters is 41.43 ml. The difference in the average prostate volume in BPH patients can be due to BPH risk factors that are not the same in each study. These risk factors include race (Egan, 2016), obesity (Jung et al., 2016) and diabetes (Sarma et al., 2009). The above risk factors are not mentioned Mao et al. (2009) and Putra et al. (2016) can be the cause of the difference in average prostate volume results when compared to the results of research conducted at Dr. Soetomo Hospital.

Research conducted at Dr. Soetomo Hospital Surabaya found a significant correlation between PSA levels and prostate volume in BPH patients (r = 0.362; p = 0.019). Another study supporting this result is Putra et al. (2016), who found a correlation between PSA levels and prostate volume in the male population at Dr. RSUPN Cipto Mangunkusumo hospital (r = 0.26; p
ABSTRACT

Diabetes insipidus in patients with traumatic severe brain injury is a fatal injury, with a mortality rate of up to 50%. About 1.5 million people are more than 50,000 deaths and 500,000 incidents of brain injury are more than 50,000 people with hypernatremia, desmopressin, ICU, diabetes insipidus, brain injury, permanent neurological sequelae. About 85% of mortality are not shown any improvements. The patient passed away in the fifth day of treatment in the Intensive Care Unit (ICU). The signs of diabetes insipidus were presented by polyuria of 300cc/hour urine production and 149mmol/s of surgery, the definitive data on the incidence of diabetes insipidus in patients with traumatic severe brain injury of Indonesia so far. In this case report, a male, 45 years old, was taken to the Emergency Installation (IRD) after experiencing a traffic accident 12 hours before being hospitalized. After so far, in this case report, a male, 45 years old, was taken to the Emergency Installation (IRD) after experiencing a traffic accident 12 hours before being hospitalized. After

A significant relationship between PSA levels and prostate volume, can be supported by one of the pathophysiological theories of BPH, namely the presence of epithelial-stromal interaction. Epithelial-stromal interaction plays a vital role in the hormonal, cellular, and molecular regulation of prostate development in both normal and neoplastic prostates (Tang & Yang, 2009). The aging process causes a gradual accumulation of prostate mass as a result of ongoing prostate gland-stromal interactions, which can be increased by various growth factors that are provided systemically through circulation or locally through the urethra (Tang & Yang, 2009). Expressions that deviate from growth factor peptides or their receptors can directly contribute to uncontrolled growth which ultimately results in BPH. Stromal cells are responsible for secreting many growth factors such as fibroblast growth factors, growth factors such as insulin I and II, and tumor growth factors, which act automatically on the stroma itself and adjacent glandular cells to induce proliferation (Tang & Yang, 2009). The proliferation of these cells causes excessive prostate volume increase in BPH patients, causing clinical manifestations that interfere with and reduce the quality of life of patients.

There are several limitations to this study. First, we evaluated PSA and prostate volume-based only on medical record data. Therefore, our sample size depends on the completeness of the data written in the medical record. Second, prostate parameter data is only taken at one time. The best way to monitor the prostate growth pattern would be to perform a longitudinal study, where all of the participants could be measured and followed for several years in order to obtain an accurate growth rate (Zhang et al., 2013). Longitudinal research in the future is expected to complement the results of this cross-sectional study.

CONCLUSION

In conclusion, serum PSA levels have a strong relationship with prostate volume in BPH patients. The average serum PSA level and prostate volume obtained in this study are slightly different from studies that have been done in several other areas before. The researcher suggests that further research be conducted on BPH in Indonesia.
